

What is Container?

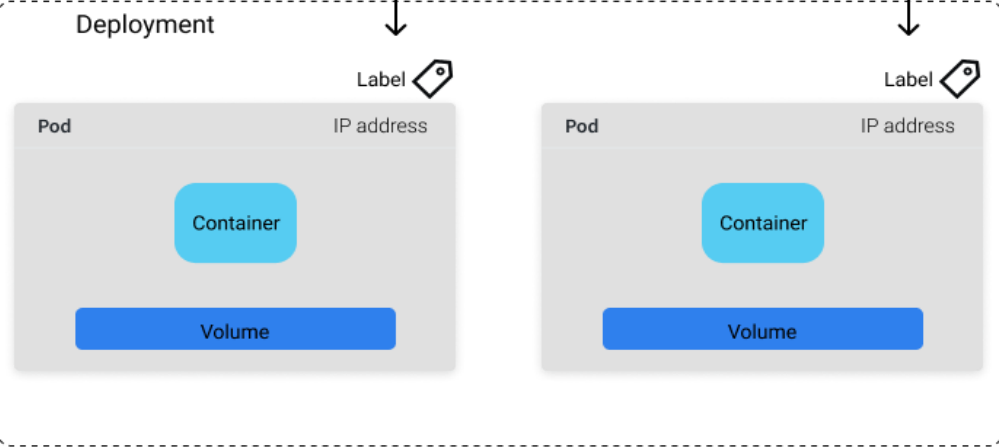

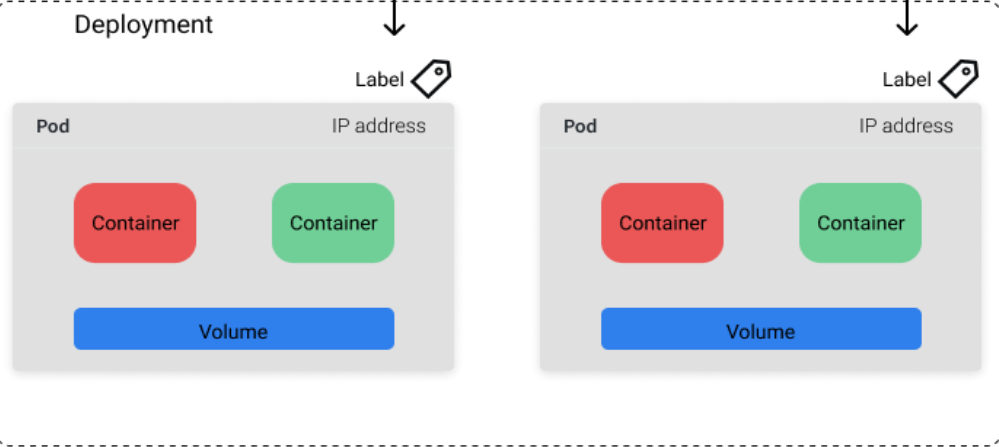

Problems does Container really solve?

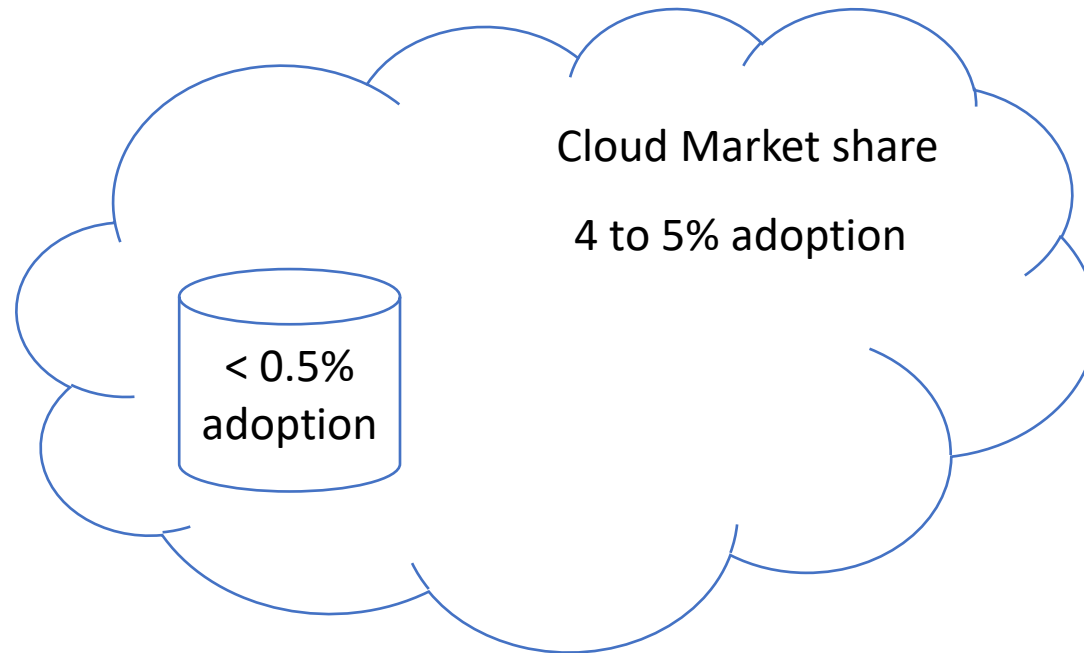

- Compatibility of each service with the libraries and dependencies of OS (One service requires versionX of OS library. Another service - versionY of same library)
- Each service has and can manage its required OS dependencies for itself, bundled and isolated in its own container
- Compatibility of each service with the libraries and dependencies of OS
- Change the components without affecting the other services.
- Change underlying OS without affecting any of the services.
